Technical notes on the `amsmath` package

American Mathematical Society

1999/10/29

1   Introduction

These notes are miscellaneous remarks on some technical questions applicable to version 2.0 of $\mathcal{AMS}$-LATEX.

2   Deprecated and disallowed commands

Certain commands that were in the `amstex` package (the predecessor, in $\mathcal{AMS}$-LATEX 1.0 and 1.1, of the `amsmath` package) were moved into `amsxtra` because they seemed to be little-used relics: `\accentedsymbol`, "sup accents" (`\sptilde`, `\sphat`, etc.).

Certain other commands—e.g., `\over`, `\pmatrix`, and `\cases`—are changed by the `amsmath` package to produce warning messages or error messages, depending on their history; these are discussed in more detail in the following sections.

3   Why do `\matrix`, `\pmatrix`, and `\cases` stop working when I add the `amsmath` package?

If you used the `plain.tex` versions of `\matrix`, `\pmatrix`, or `\cases` in a document and then later converted the document to use the `amsmath` package (or one of the AMS documentclasses, which automatically call the `amsmath` package internally), the instances of those commands will produce error messages. The problem is that when LATEX was originally created, it adopted most of its mathematics features straight from `plain.tex`. But in the case of `\matrix`, `\pmatrix`, `\cases` this was a mistake—the `plain.tex` syntax for them is decidedly non-LATEX in style, for example the fact that they use `\cr` instead of `\\` to mark line breaks, and they don't use `\begin` and `\end`. In basic LATEX this mistake will be perpetuated at least until LATEX3 appears, in order to avoid breaking existing documents. But no existing documents that were written with the `amsmath` package have that syntactic problem, as `amsmath` provides proper LATEX-syntax versions of `\matrix` and the others. The possibility of optionally allowing the `plain.tex` variants to make document conversion easier seems ill-advised since those variants are so blatantly wrong in a LATEX context. The `array` environment ought to have been used instead.

4   Why do `\over`, `\atop`, `\above` [...withdelims] give a warning when I add the `amsmath` package?

Using the six generalized fraction commands `\over`, `\overwithdelims`, `\atop`, `\atopwithdelims`, `\above`, `\abovewithdelims` is not really a good idea in LATEX, for reasons explained below. I construe LATEX's provision of `\frac`, and

the lack of any mention in the LaTeX book of the primitive fraction commands, as an implicit injunction against their use, although I don't think Lamport actually spent a lot of time pondering the issue, and the basic LaTeX version of `\frac` provides access only to `\over`, not to `\atop`, `\above`, or the `withdelims` variants. The `amsmath` package, however, provides a `\genfrac` command that gives user-level access to all six of the generalized fraction primitives in a way that conforms to the syntactic conventions followed by all other LaTeX commands.

Not only is the unusual syntax of the TeX primitives rather out of place in LaTeX, but furthermore that syntax seems to be responsible for one of the most significant flaws in TeX's mathematical typesetting capabilities: the fact that the current mathstyle at any given point in a math formula cannot be determined until the end of the formula, because of the possibility that a following generalized fraction command will change the mathstyle of the *preceding* material. To cite two of the worst side effects: `\mathchoice` must actually typeset all four of its arguments, instead of being able to immediately select only one; and, were it possible to always know the current math style at a given point, math font selection would be greatly simplified and the upper limit of 16 different math font `\fam`s would never be a problem as `\text,script[script]font` assignments for any `\fam` could take immediate effect and therefore could be changed arbitrarily often within a single formula. More concretely, math font selection difficulties are responsible for many of the more convoluted passages in the source code of LaTeX's NFSS (that does font loading on demand) and of the `amsmath` package, and by extension it has historically been responsible for significant delays in making new features available to end users and for making those features more prone to bugs.

There are additional bad consequences following from the syntax of those generalized fraction commands that only become evident when you do some writing of nontrivial macros for math use. For example, as things currently stand you cannot measure the size of any object in math without going through `\mathchoice` and *leaving and reentering math mode* via `\hbox{$` (which then introduces complications regarding `\everymath` and `\mathsurround`). And it seems that uncertainty about the current mathstyle is the only barrier to allowing the use of mu units with `\vrule`, to make vertical struts in constructing compound symbols or notation. And so on and so forth.

5   The `fleqn` option and `\mathindent`

Strictly speaking, the `amsmath` package doesn't use `\mathindent` to control the left indent of displayed equations when the `fleqn` option is in effect: it uses an internal parameter `\@mathmargin` instead. However, for compatibility with existing LaTeX documentation, `amsmath` turns `\mathindent` into an alias for `\@mathmargin`. There is a small risk here: In the plain LaTeX implementation, `\mathindent` is a dimen register, but with `amsmath` `\@mathmargin` is a skip register and, by association, so is `\mathindent`. If any package or documentclass uses `\mathindent` in a way that depends on it being a dimen register, when used in conjunction with the `amsmath` package it may be vulnerable to a well-known pitfall having to do with the primitive TeX lookahead for a `plus` or `minus` key word. However if the standard LaTeX commands `\setlength` and `\addtolength` are used to modify `\mathindent` then this problem will not arise.

6   Why can't I use abbreviations for `\begin{align}` … `\end{align}`?

Authors often like to use abbreviations such as `\beq \eeq` for `\begin{equation} \end{equation}`. For some environments defined by the `amsmath` package, such

as `align`, `gather`, `multline`, and others of the same general type, this does not work: An attempt to define `\bal \eal` as shorthand for `\begin{align}` `\end{align}` will fail with a puzzling error message. This has to do with unfortunately nontrivial technical complications: the given environments must read their contents as a delimited macro argument because they do multipass processing of the contents using algorithms inherited from Spivak's `amstex.tex`. The obvious solution—substitution of different algorithms that do box shuffling instead of token shuffling for the multipass calculations—would require rewriting these display environments from the ground up; while that is a worthy goal, it was beyond the original scope of the $\mathcal{AMS}$-LaTeX project. Work is under way on an auxiliary package called `breqn` that addresses not only this problem but a number of others; at the time of this writing, however [September 1999] it has only progressed as far as a beta release.

Some workarounds:

- `\def\bal#1\eal{\begin{align}#1\end{align}}`
- Define `\newcommand{\env}[2]{\begin{#1}#2\end{#1}}` and then use `\env{align}{...}`

7 The `upref` package

The reason for splitting out the `upref` package instead of automatically incorporating it in the `amsart` and `amsbook` classes is this: It involves low-level surgery on an important LaTeX command. This means that if ever this command changes in the future (as it did between versions 2.09 and 2e of LaTeX) we have a maintenance problem. And the benefit that `upref` provides is something that most end users don't care much about.

8 The `amsintx` package

After a very preliminary trial release the `amsintx` package was withdrawn to await further development. It is still considered a worthy project but has simply not yet made it to the head of the priority queue in the AMS LaTeX development program, as it has had to contend with a number of other equally worthy projects for development time.

9 Hyphenation in the documentation

Hyphenation was allowed for certain long command names in `amsldoc.tex`; this presented technical difficulties because LaTeX normally deactivates hyphenation for tt fonts. The method chosen to reinstate hyphenation was to turn off the encoding-specific function `\OT1+cmtt` that disables the `\hyphenchar` for tt fonts; see the definition of `\allowtthyphens` in `amsdtx.dtx`. Then a list of all tt words in the document was gathered (from the `.idx` file, produced by the `\cn`, `\fn`, `\pkg`, etc. commands) and `\showhyphens` was applied to this list. The result was another list in the resulting TeX log, containing those words in a form suitable for the argument of `\hyphenation`. That list was then edited by hand to overrule undesirable hyphenations; words with acceptable hyphenations were dropped from the list, as they don't need to be repeated there.
